Abstract

The alkyl chain carrying ligands *N,N*-di(pyridin-2-yl)butanamide (LC₄) and *N,N*-di(pyridin-2-yl)decanamide (LC₁₀) were combined with NCS⁻ co-ligands to form the neutral heteroleptic Fe(II) complexes *trans*-[Fe^{II}(LC₄)₂(NCS)₂] (**1C₄**) and *trans*-[Fe^{II}(LC₁₀)₂(NCS)₂] (**1C₁₀**). Variable temperature crystallographic studies revealed that **1C₄** is in the orthorhombic space group *Pna*2₁ between 85-200 K whereas **1C₁₀** is in the monoclinic space group *P*2₁/*c* between 85-140K. The average Fe-N bond lengths suggest that at 85 K **1C₄** contains LS Fe(II) centres; However, the *ca.* 0.18 Å increase in the average Fe-N bond lengths between 85 and 120 K suggest a spin-transition to the HS state occurs within this temperature interval. **1C₁₀** contains LS Fe(II) centres between 85 and 105 K. Upon warming from 105 to 140 K the average Fe-N bond lengths increase by *ca.* 0.19 Å, which suggests a spin-transition to the HS state. Solid-state magnetic susceptibility measurements showed that **1C₄** undergoes semi-abrupt spin-crossover with $T_{1/2} = 127.5$ K and a thermal hysteresis of *ca.* 13 K whereas, **1C₁₀** undergoes an abrupt spin-crossover with $T_{1/2} = 119.0$ K, and is also accompanied by thermal hysteresis of *ca.* 4 K. The crystallographic and magnetic data show that the length of the complex's alkyl chain substituents can have a large impact on the structure of the crystal lattice as well as a subtle effect on the $T_{1/2}$ value for thermal spin-crossover.

Introduction

The spin-crossover¹ (SCO) phenomenon is most commonly encountered in octahedral Fe(II) species where a reversible transition between the quantum mechanical ground state (low-spin (LS) state), and the thermodynamically stable high-spin (HS) state can be achieved by application of external influences such as temperature,² pressure,³ irradiation^{4,5} and applied magnetic fields.⁶ Cooperative SCO systems rely on strong intermolecular interactions such as hydrogen bonds and $\pi\cdots\pi$ contacts and this cooperativity can result in an abrupt spin-transition often accompanied by thermal hysteresis. This enables bistability between the two spin states, making SCO materials ideal candidates for use as switches or memory devices. This transition between the LS and HS states, with a subsequent change in the Fe(II) to ligand donor atom distance, results in a significant change in the material's magnetic and electric dipole moments, conductivity and optical properties.^{7,8} This makes SCO materials attractive targets for both molecular-based spintronic devices⁹⁻¹¹ and hybrid multifunctional materials incorporating a secondary function such as luminescence or chirality.¹²

In 2005 Réal and co-workers investigated Fe(II) complexes of di(pyridin-2-yl)amine (dpa), and showed that *cis*-[Fe^{II}(dpa)₂(NCS)₂] underwent gradual and incomplete thermal SCO with a $T_{1/2}$ value of 88 K.¹³ This $T_{1/2}$ value and nature of the spin transition can be changed by modification of the amine group of the dpa ligand with notable examples including derivatised dpa/triazine ligands including: *trans*-[Fe^{II}(DPT)₂(NCS)₂]·CH₃OH which undergoes a gradual incomplete spin-transition with $T_{1/2}$ of 150 K;¹⁴ α -*trans*-[Fe^{II}(DBB)₂(NCS)₂] exhibiting a complete abrupt spin-transition ($T_{1/2}$ = 170 K);¹⁵ β -*trans*-[Fe^{II}(DBB)₂(NCS)₂] showing a gradual but complete spin transition ($T_{1/2}$ = 300 K);¹⁵ and *trans*-[Fe^{II}(Cladpat)₂(NCS)₂] undergoing a complete spin transition with a $T_{1/2}$ value of 178 K¹⁶ (DPT = 6-phenoxy-*N*²,*N*²,*N*⁴,*N*⁴-tetra-2-

pyridinyl-1,3,5-triazine-2,4-diamine; DBB= (N^2,N^2,N^4,N^4 -tetrabenzyl- N^6,N^6 -di(pyridin-2-yl)-1,3,5-triazine-2,4,6-triamine; and Cladpat = 6-chloro- N' -phenyl- N,N -di(pyridin-2-yl)-1,3,5-triazine-2,4-diamine). The work outlined above set a precedent for investigation of Fe(II) systems that incorporate derivatised dpa ligands and NCX co-ligands (where X = is typically S, Se, BH₃) in an attempt to tailor the magnetic properties of the resultant materials. This approach allows for the possibility of multifunctionality through selection of a desirable N -substituent, such as alkyl chains, on to the parent dpa scaffold.

A number of studies have focussed on utilising the conformational changes of alkyl chain containing materials to: probe the relationship between SCO and thermotropic liquid crystal behaviour;¹⁷⁻²⁰ develop dual functioning SCO-active materials such as those found in Langmuir-Blodgett films;²¹ and study biomimetic models of phospholipid membranes.^{22,23} A recent example by Cl rac *et al.* of an iron(II) complex functionalised with decyl alkyl chains, [Fe(C₁₀-pbh)₂] (C₁₀-pbh = (1Z, $N'E$)-4-(decyloxy)- N' -(pyridin-2-ylmethylene)-benzohydrazone)), had a SCO transition with a 35 K thermal hysteresis near room temperature with phase dependent magnetic properties.²⁴ It is encouraging that the alkyl chain component of such materials does not necessarily inhibit any desirable SCO properties such as abrupt/hysteretic spin-transitions and cooperative lattice effects.²⁵⁻²⁹ Here we report a family of SCO-active, mononuclear, neutral complexes of Fe(II) based on the alkyl chain containing ligands N,N -di(pyridin-2-yl)butanamide (LC₄) and N,N -di(pyridin-2-yl)decanamide (LC₁₀) (Scheme 1) with formula [Fe^{II}(LC_{*x*})₂(NCS)₂] where $x = 4$ (**1C₄**) or 10 (**1C₁₀**).

Experimental

General

All reagents were purchased from Sigma-Aldrich (Merck) and were used as received without further purification. All solvents were purchased from Fisher Scientific. Methanol was dried over 4 Å molecular sieves (20% w/w) for a minimum period of 48 h before use in synthetic procedures. All synthetic procedures were done under aerobic conditions unless otherwise stated. ^1H and ^{13}C NMR spectra were recorded in deuteriochloroform (CDCl_3) containing 1% trimethylsilane (TMS) on a Bruker Avance 400 MHz spectrometer and can be found in Figures S14-S21. The following abbreviations are used for the multiplicities: s = singlet, d = doublet, t = triplet, q = quartet, quin = quintuplet, sext = sextet and m = multiplet. Mass spectrometry was collected on a Bruker MicroTOF instrument with positive mode electrospray ionisation and using methanol as the eluent (Fig. S22 and S23). A Perkin Elmer Spectrum 65 FT spectrophotometer was used to obtain IR data at room temperature.

Elemental analysis

Elemental analysis was obtained by MEDAC LTD analytical and chemical consultancy service.

X-ray crystallography

X-ray crystallography was conducted on a sample of fresh single crystals of **1C₄** and **1C₁₀**. The single crystal was selected from a vial containing the methanolic mother liquor under a nitrogen atmosphere and placed straight into oil to avoid drying. Variable temperature X-ray diffraction data for **1C₄** were collected using an AFC12 goniometer and a HyPix-600HE detector, FR-E+ SuperBright Molybdenum X-Ray generator and a highly focused beam (70 μm)

achieved with VariMax VHF optics. The diffractometers were also equipped with the Oxford Cryosystems Cobra. Variable temperature X-ray diffraction data for **1C₁₀** were collected using an AFC12 goniometer and a HyPix-600HE detector, FR-E+ SuperBright Molybdenum X-Ray generator and a highly focused beam (70 μ m) achieved with VariMax VHF optics. **1C₄·85K** was solved using intrinsic phasing and refined by full-matrix least-squares on F^2 with SHELXL.³⁰ **1C₄·120K** was solved and refined using Olex2^{31,32} and **1C₄·200 K** was solved using Olex2³² and refined by full-matrix least-squares on F^2 with SHELXL.³⁰ **1C₁₀·85K**, **1C₁₀·105K** and **1C₁₀·140K** were solved using direct methods with SHELXS³³ and refined by full-matrix least-squares on F^2 with SHELXL.³⁰ Crystallographic and refinement parameters; selected bond length and angles; and selected intermolecular contact distances for all the crystal structures are located in Tables 1-6. CCDC 1947560-1947565 contains the supplementary crystallographic data for this paper. The data can be obtained free of charge from The Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/structures.

Magnetic Susceptibility Measurements

Variable-temperature magnetic susceptibility measurements were performed on a Quantum Design MPMS 7T SQUID magnetometer over the temperature range 50-340 K at a 5 K min⁻¹ rate for **1C₄** and **1C₁₀** under an applied field of 0.1 T. The crystals of **1C₄** and **1C₁₀** were in methanol under a nitrogen atmosphere but were filtered, air dried quickly and then encased in Vaseline to avoid any torquing effects. These samples were held in a capsule at the centre of a drinking straw fixed to the sample rod. The magnetometer was calibrated by either a standard palladium sample or CuSO₄·5H₂O and diamagnetic corrections were applied using Pascal's constants. The molecular weight used in the magnetic measurements were based on the solvated forms of **1C₄** and **1C₁₀** as defined by the microanalysis (**1C₄·2H₂O** and **1C₁₀·H₂O**).

Synthetic procedures

Scheme 1 Synthetic route to ligands LC_x ligands from di(pyridin-2-yl)amine (dpa), where C_x is the number of carbon atoms in the alkyl chain substituent including that of the carbonyl group.

***N,N*-Di(pyridin-2-yl)butanamide (LC_4):** Di(pyridin-2-yl)amine (dpa) (1.712 g, 10 mmol) and triethylamine (Et_3N) (2.65 cm³, 19 mmol) were dissolved in 10 cm³ of CH_2Cl_2 , cooled over an ice bath and placed under an atmosphere of N_2 . Butyryl chloride (1.03 cm³, 10 mmol) was dissolved in 10 cm³ of CH_2Cl_2 and added to the dpa/ Et_3N solution via syringe. The resulting solution was stirred for 12 h under N_2 . 50 cm³ of a saturated aqueous ammonium chloride solution was added to the reaction solution and the organic phase was separated. The aqueous phase was then extracted with 2 x 20 cm³ of CH_2Cl_2 and the organic extracts combined. The combined organic phases were then extracted with 3 x 30 cm³ of a 10% (w/v) aq. NaCl solution. The organic phase was then washed firstly with 50 cm³ of 0.1 M aq. NaOH and finally 50 cm³ of 0.1 M aq. HCl solution before the organic phase was dried over anhydrous MgSO_4 . This solution was then gravity filtered and the solvent evaporated under reduced pressure to afford LC_4 as a pale orange solid. Yield = 1.86 g, 7.7 mmol (77%). ¹H NMR (CDCl_3 , 400 MHz) δ : 8.45 (ddd, $J = 4.9, 2.0, 0.7$ Hz, 2H), 7.76 (td, $J = 7.8, 2.0$ Hz, 2H), 7.51 (d, $J = 8.1$ Hz, 2H), 7.19 (ddd, $J = 7.5, 4.8, 1.0$ Hz, 2H), 2.29 (t, $J = 7.3$ Hz, 2H), 1.70 (sext, $J = 7.6$ Hz,

2H), 0.91 (t, $J = 7.4$ Hz, 3H). ^{13}C NMR (CDCl_3 , 100 MHz) δ : 173.7, 154.8, 149.0, 138.0, 122.3, 121.9, 38.1, 18.5, 13.7, MS (ESI⁺) (MeOH): m/z calcd for $\text{C}_{14}\text{H}_{15}\text{N}_3\text{O}$ [M]⁺, 241.29; found, 264.07 [$M + \text{Na}$]⁺, 505.17 [$2M + \text{Na}$]⁺.

***N,N*-Di(pyridin-2-yl)decanamide (LC₁₀):** LC₁₀ was prepared via the same procedure as LC₄, using decanoyl chloride (2.08 cm³, 10 mmol). The compound was afforded as a yellow-brown solid. Yield = 2.44 g, 7.5 mmol (75%). ^1H NMR (CDCl_3 , 400 MHz) δ : 8.45 (ddd, $J = 4.9, 2.0, 0.7$ Hz, 2H), 7.76 (td, $J = 7.8, 2.0$ Hz, 2H), 7.51 (d, $J = 8.1$ Hz, 2H), 7.18 (ddd, $J = 7.5, 4.8, 1.0$ Hz, 2H), 2.30 (t, $J = 7.4$ Hz, 2H), 1.66 (quin, $J = 7.5, 7.0$ Hz, 2H), 1.23 (m, 12H), 0.87 (t, $J = 7.2$ Hz, 3H). ^{13}C NMR (CDCl_3 , 100 MHz) δ : 173.7, 154.8, 148.9, 138.5, 122.4, 121.8, 36.3, 31.8, 29.4, 29.3, 29.2, 25.1, 22.6, 14.0. MS (ESI⁺) (MeOH): m/z calcd for $\text{C}_{20}\text{H}_{27}\text{N}_3\text{O}$ [M]⁺, 325.46; found, 326.2 [$M + \text{H}$]⁺, 349.20 [$M + \text{Na} + \text{H}$]⁺, 364.20 [$M + \text{K}$]⁺.

[Fe^{II}(LC₄)₂(NCS)₂] (1C₄): Fe(BF₄)₂·6H₂O (33.8 mg, 0.1 mmol) and ascorbic acid (5 mg, 0.003 mmol) were placed into a 10 cm³ round bottomed flask, dissolved in 2 cm³ of dry methanol and placed under a nitrogen atmosphere. LC₄ (48.2 mg, 0.2 mmol) was added to a second 10 cm³ round bottomed flask, dissolved in 2 cm³ of dry methanol and placed under a nitrogen atmosphere. KSCN (19.4 mg, 0.2 mmol) was added to the solution of Fe(BF₄)₂·6H₂O and ascorbic acid, which was subsequently left for 10 min. Next, the solution containing the Fe(BF₄)₂·6H₂O was transferred via syringe to the solution containing LC₄. After 12 h, single crystals of **1C₄** had formed. For microanalysis, infrared measurements and yield calculations these crystals were collected via glass pipette and placed onto filter paper, quickly dried in air and then placed in a 20 cm³ glass vial and purged with nitrogen gas. Although the single crystal used for X-ray diffraction studies was found to be solvate free (see below) the air-dried crystals had acquired two water solvates, affording **1C₄·2H₂O**. Elemental analysis (air-dried crystals) found: C, 51.91; H, 4.38; N, 16.28. Calc. for $\text{C}_{30}\text{H}_{30}\text{FeN}_8\text{O}_2\text{S}_2\cdot 2\text{H}_2\text{O}$: C, 52.17; H, 4.96;

N, 16.23 %. IR (air-dried crystals) ν_{\max} (cm⁻¹) 3077vw, 2961w, 2868w, 2045vs, 1693vs, 1600s, 1565m, 1481s, 1463vs, 1438vs, 1378s, 1316vs, 1238vs, 1198vs, 1157s, 1101s, 1057m, 1017s, 970w, 886m, 802s, 783m, 765s, 690m, 650m.

[Fe^{II}(LC₁₀)₂(NCS)₂] (1C₁₀): 1C₁₀ was prepared via the same procedure as 1C₄, using LC₁₀ (65.1 mg, 0.2 mmol) and all subsequent measurements performed in a similar way. The single crystal used for the X-ray diffraction studies was solvate free whereas the air-dried crystals had acquired one water solvate molecule, affording 1C₁₀·H₂O. Elemental analysis (air dried crystals) found: C, 59.58; H, 6.55; N, 13.24. Calc. for C₄₂H₅₄FeN₈O₂S₂·H₂O: C, 59.99; H, 6.71; N, 13.33 %. Fig. 1 Molecular structure of **1C₄·85K** with atom labels. Hydrogen atoms omitted for clarity. Legend: iron, turquoise; nitrogen, blue; carbon, grey; oxygen, red; sulfur, yellow. This is representative of the numbering in **1C₄·120K** and **1C₄·200K**.

Variable temperature crystallography at 85K (**1C₄·85K**), 120 K (**1C₄·120K**) and 200 K (**1C₄·200K**) were performed on the same single crystal. **1C₄·85K**, **1C₄·120K** and **1C₄·200K** are all in the orthorhombic space group *Pna*2₁ with the asymmetric unit containing one complete *trans*-[Fe^{II}(LC₄)₂(NCS)₂] molecule (Table 1). The neutral, heteroleptic complex is formed by two bidentate chelating LC₄ ligands in equatorial positions and two NCS⁻ anions in the *trans* axial sites to form a slightly distorted octahedron with an FeN₆ core (Fig. 1). The unit cell of **1C₄·85K** is depicted in Fig. S1. The two LC₄ ligands coordinate via the pyridyl nitrogen atoms (N1, N2, N4 and N5) and the NCS⁻ ligands coordinate through the N atom of the nitrile groups (N3 and N6). A selection of bond lengths and angles for the three crystal structures can be found in Table 2. There is evidence of a spin-transition between 85 K and 120 K with **1C₄·85K** and **1C₄·120K** having average Fe-N bond lengths of 1.994 and 2.178 Å respectively (Table 2); typical values for an Fe(II) ion undergoing a LS to HS spin-transition.^{4,16,27,34,35} In **1C₄·200K** the

Fe-N bond lengths are similar to that of **1C₄·120K**, suggesting the presence of a central HS Fe(II) ion (Table 2).

Table 2 Selected angles and bond lengths for **1C₄·85K**, **1C₄·120K** and **1C₄·200K**.

^a Octahedral distortion parameters are obtained using the equation: $\Sigma = \sum_{i=1}^{12} (|90 - \theta_i|)$, (θ_i = N-

Fe-N) where perfect octahedrons produce a value $\Sigma = 0^\circ$ and deviation from this value coincides with structural deformation of the coordination polyhedron.

1C₄·85K has a distorted octahedral geometry, with an associated octahedral distortion parameter $\Sigma = 29.4^\circ$. The spin transition in the Fe(II) ions between 85-120 K is accompanied by further deformation of the FeN₆ polyhedron. This is demonstrated by the increase in the parameter Σ to 39.0° in **1C₄·120K** and 39.7° in **1C₄·200K**.^{5,35,36} The lack of structural transformation between the 120 and 200 K structures of **1C₄** suggests that the spin transition is mostly complete by 120 K and the vast majority of the Fe(II) centres will be in the thermodynamically stable HS state.

Fig. 2 Structural changes in the LC₄ ligands as the LS to HS conversion takes place in a single crystal of **1C₄·85K** (left) and **1C₄·120K** (right).

The LC₄ and NCS⁻ ligands also distort to accommodate the spin transition (Fig. 2). The pyridyl moieties of the ligands rotate about their free axis with the bridging N7 and N8 atoms to accommodate the increasing Fe-N distances for the HS Fe(II) ions. This is manifested by a decrease in the N1-N7-N2 and N4-N8-N5 angles for each ligand unit (Fig. 2). For **1C₄·85K** the N1-N7-N2 angle is 71.3(4)°, rising to 76.4(2)° in **1C₄·120K**, whilst the N1-Fe1-N2 angle in **1C₄·85K** is 86.4(3)° and decreases to 83.1(2)° in **1C₄·120K**. In **1C₄·200K** the angles reported above are similar to that in **1C₄·120K** (N1-N7-N2 = 76.5(3)° and N4-N8-N5 = 76.0(3)°). The Fe-N-C angles, between the central Fe(II) ion and the coordinated SCN group, in **1C₄·85K** are 156.0(8) and 156.3(7)° whereas in **1C₄·120K** these angles decrease to 145.5(4) and 147.1(4)°, to accommodate the change in spin state, which is a common feature noted by Brooker et al.³⁷ In **1C₄·200K** the Fe-N-C angles remain similar to that in **1C₄·120K** with values of 145.9(6) and 148.8(6)° (Table 2).

Table 3 Selected intermolecular contact distances for **1C₄**.

	1C₄·85K	1C₄·120K	1C₄·200K
$\pi \cdots \pi$ (Å) ^a	3.500(5)	3.557(3)	3.589(4)
O \cdots C (Å)	3.138(11)	3.116(6)	3.127(9)
O \cdots H-C (°)	126.6(6)	122.5(1)	124.0(5)
Fe \cdots Fe (Å) ^b	8.3066(6)	8.5587(4)	8.6178(4)

^a Minimum pyridyl centroid \cdots centroid distance. ^b Minimum distance between Fe atoms.

Fig. 3 a) The centroid...centroid π ... π contact between pyridyl groups of **1C₄**. b) 2D sheet of short C-H...O contacts in the *ab* plane between complexes of **1C₄**. c) 1D chain of complexes of **1C₄·85K** as viewed along the *a* axis. These are representative of the similar interactions seen in **1C₄·120K** and **1C₄·200K**. Legend: iron, turquoise; nitrogen, blue; carbon, grey; oxygen, red; sulfur, yellow.

Neutral complexes of **1C₄·85K** pack via short π ... π contacts between nearby pyridyl moieties, resulting in 1D “chains” of complexes propagating along the *b* axis (Fig. 3a and c). The pyridyl groups of the complexes approach each other in a slightly staggered manner and the associated centroid...centroid distance for **1C₄·85K** is 3.500(5) Å with the pyridyl groups tightly packed along the *b* axis. This π ... π contact distance gets larger as we increase temperature, with values changing from 3.500(5) Å in **1C₄·85K** to 3.557(3) Å in **1C₄·120K** and 3.589(4) Å in **1C₄·200K** (Table 3). This results in a diagonal expansion of these 1D chains of complexes along the *bc* plane with a subsequent increase in the unit cell parameters *b* and *c* and a concomitant decrease in *a*. In all of the structures there are short C-H...O contacts between the oxygen

atoms of the carbonyl moieties of the LC₄ ligands and the pyridyl C-H groups of a nearby complex (Fig. 3b).^{38,39} These C-H...O contacts range from 3.138(11) Å in **1C₄·85K** to 3.116(6) Å in **1C₄·120K** and 3.127(9) Å in **1C₄·200K**. The packing mode of the complexes at all temperatures is almost identical to that of **1C₄·85K** apart from the slightly larger intermolecular distances detailed in Table 3; expected given the spin-transition from LS to HS over this temperature range. The C-H...O contacts propagate across the *ab* plane, and in combination with the 1D $\pi\cdots\pi$ contacts along the *b* axis, form 2D networks of complexes across this crystallographic plane. The alkyl chain tails from each complex extend away from the metal centre in each direction predominantly along the *c* axis. 2D sheets of complexes then stack up the *c* axis and interdigitate their alkyl chain tails to form small regions of hydrophobicity containing aliphatic tails (Fig. 4).

Fig. 4 Packing of **1C₄** at 85 K as viewed down the *b* axis. Hydrogen atoms omitted for clarity.

Legend: iron, turquoise; nitrogen, blue; carbon, grey; oxygen, red; sulfur, yellow.

$$^aR1 = \sum ||F_0| - |F_c|| / \sum F_0, \quad ^bWR2 = \left\{ \frac{\sum [w(F_0^2 - F_c^2)^2]}{\sum [w(F_0^2)]} \right\}^{1/2}$$

Variable temperature crystallography was performed at 85K (**1C₁₀·85K**), 105 K (**1C₁₀·105K**) and 140 K (**1C₁₀·140K**) on the same single crystal of **1C₁₀** in a similar vein to that reported above for **1C₄**. **1C₁₀·85K**, **1C₁₀·105K** and **1C₁₀·140K** are in the monoclinic space group *P2₁/c* (Table 4). The *trans*-[Fe^{II}(LC₁₀)₂(NCS)₂] molecular structure of the complex is similar to that of **1C₄** (Fig. S2) with an identical coordination sphere and steric arrangement of the ligands, differing only in the length of the alkyl chain tail. In **1C₁₀·85K**, **1C₁₀·105K** and **1C₁₀·140K** the asymmetric unit

contains one half of the molecular unit, with an inversion centre located on the central Fe(II) ion. The unit cells for **1C₁₀·85K**, **1C₁₀·105K** and **1C₁₀·140K** are shown in Figs. S3, S4 and S5, respectively. It is clear that the central Fe(II) ion is low-spin in **1C₁₀·85K** and **1C₁₀·105K**, with average Fe-N bond lengths of 1.979, 1.982 Å respectively (Table 5). The significantly larger average Fe-N bond length of 2.172 Å found in **1C₁₀·140K** (Table 5) suggests that the system is completely HS at 140 K and that a relatively abrupt spin-transition between 105 K and 140 K must occur. The molecular units of **1C₁₀·85K**, **1C₁₀·105K** and **1C₁₀·140K** have a distorted octahedral geometry with $\Sigma = 28.4^\circ$, 28.5° and 35.1° respectively, supporting the conclusion of a spin-transition between 105 K and 140 K.

The packing in **1C₁₀·85K**, **1C₁₀·105K** and **1C₁₀·140K** is directed by the same short contacts as **1C₄** (Table 6 and Figs. S6 and S7). Intermolecular $\pi \cdots \pi$ contacts along the *b* axis are 3.5670(10), 3.5770(13) and 3.6336(11) Å (Fig. S6), while the shortest C-H \cdots O contacts are 3.115(1), 3.121(2) and 3.144(2) Å for **1C₁₀·85K**, **1C₁₀·105K** and **1C₁₀·140K** respectively (Table 6 and Fig. S7). The similarity in packing between the LS structures of **1C₁₀·85K** and **1C₁₀·105K** is expected and the 2D networks of complexes formed through the intermolecular contacts are separated by their *trans* alkyl chain tails, which extend mostly down the *a* axis to form layers in the *bc* plane, where the 2D sheets of complexes are between two regions of hydrophobic alkyl chains (Fig. 5).

Table 5 Selected bond lengths and angles for **1C₁₀·85K**, **1C₁₀·105K** and **1C₁₀·140K**.

O \cdots H-C (°) ^b	130.20(7)	130.37(9)	125.78(8)
Fe \cdots Fe (Å) ^c	8.2351(2)	8.2544(3)	8.5341(2)
Fe \cdots Fe (Å) ^d	15.1219(6)	15.1476(13)	15.1845(5)

^a Minimum contact distances between intermolecular pyridyl moieties taken between centroids. ^b Shortest interatomic O \cdots C contacts between nearby carbonyls and pyridyl rings.

^c Minimum contact distance between Fe atoms. ^d Shortest Fe \cdots Fe contacts between molecules in parallel 2D networks separated by alkyl chain regions.

The only significant difference between the LS (**1C₁₀·85K** and **1C₁₀·105K**) and HS (**1C₁₀·140K**) structures are the larger interatomic distances associated with the $\pi\cdots\pi$ contacts, C-H \cdots O contacts and Fe \cdots Fe distances, which are larger in **1C₁₀·140K** than in **1C₁₀·105K** and **1C₁₀·85K** as expected (Table 6). In **1C₁₀** at all temperatures the 2D networks of LS Fe(II) centres are separated by alkyl chains along the *a* axis (Figs. S3-S5 and Figs. S8-10), with the LS and HS structures of **1C₁₀** packing identically (Fig. 6)

Fig. 6 Overlay of the LS (blue) and HS (orange) asymmetric units of **1C₄** (left) and **1C₁₀** (right). Hydrogen atoms omitted for clarity. Structures were overlaid using the atomic coordinates of the FeN₆ cores in Olex2.^{31,32}

For LS **1C₁₀·105K** the Fe-N-C angles of the coordinated NCS⁻ anion are 158.62(12)°, whereas for HS **1C₁₀·140K** these angles decrease to 150.26(11)°. These changes in the Fe-NCS angles of *trans* isomers are in-line with the observations in **1C₄** and are in agreement with the analysis of *trans*-[Fe^{II}(Rdpt)₂(NCX)₂] complexes (Rdpt = 4-(R)-3,5-di(2-pyridinyl)-4H-1,2,4-triazole, X = S, Se or BH₃) performed by Rodríguez-Jiménez and Brooker.³⁷ Although there may be a relationship between the Fe-NCS angle and the spin state or even the SCO activity of the heteroleptic complexes of this sort, it remains unclear whether this is applicable to all systems

with the general formula *cis/trans*-[Fe^{II}(Rdpa)₂(NCX)₂]. The following coordination compounds: *trans*-[Fe(bdpp)(NCS)₂] (bdpp = bis(2',2''-dipyridylamine)pyrimidine),⁴⁰ *cis*-[Fe^{II}(DDE)₂(NCSe)₂] (DDE = *N*²,*N*²,*N*⁴,*N*⁴-tetraethyl-*N*⁶,*N*⁶-di(pyridin-2-yl)-1,3,5-triazine-2,4,6-triamine),⁴¹ *trans*-[Fe^{II}(DPPyT)(NCS)₂] and *trans*-[Fe^{II}(DPPyT)(NCSe)₂] (DPPyT = 1-[4,6-bis(dipyridin-2-ylamino)-1,3,5-triazin-2-yl]pyridin-4(1*H*)-one)¹⁴ do not show a consistent decrease in the Fe-NCX angles with the transition from LS to HS in these SCO-active complexes. This suggests that the distortion of the Fe-NCS angles in **1C₄** and **1C₁₀** between the LS and HS states may be relevant only to the systems reported here. Overall it is clear from the variable temperature crystallographic studies that both complexes undergo a spin-transition between 85 K and 120 K for **1C₄** and between 105 K and 140 K for **1C₁₀**.

Magnetic studies

From the crystallographic data it is clear that we would expect a spin-transition between 85 K and 120 K for **1C₄** and between 105 K and 140 K for **1C₁₀**. To confirm this variable temperature magnetic susceptibility measurements were obtained on single crystals of **1C₄** and **1C₁₀** down to 50 K at a heating/cooling rate of 5 K min⁻¹ in an applied DC field of 0.1 T (Fig. 7). The single crystals were removed from the mother liquor and dried in air momentarily before being analysed so that oxidation or decomposition was minimised. Upon cooling from 300 K, **1C₄** has a $\chi_{\text{M}}T$ value of 3.50 cm³ mol⁻¹ K down to 175 K, corresponding to a fully HS Fe(II) system. Below 175 K the $\chi_{\text{M}}T$ value decreases slightly to ca. 3.30 cm³ mol⁻¹ K at 150 K before a small plateau region is established down to 140 K. An abrupt spin transition then occurs between 140 and 100 K as the value of $\chi_{\text{M}}T$ decreases from 3.25 to 0.13 cm³ mol⁻¹ K, which signifies an almost quantitative LS population of Fe(II) centres. The value of $\chi_{\text{M}}T$ then subtly decreases to 0.09 cm³ mol⁻¹ K at 50 K. To check for thermal hysteresis, the samples were then reheated from 50 K. Upon heating, the $\chi_{\text{M}}T$ value rises gradually, reaching 0.45 cm³ mol⁻¹ K at

122 K. An abrupt spin transition then occurs between 122 and 146 K and the value of $\chi_M T$ reaches $3.22 \text{ cm}^3 \text{ mol}^{-1} \text{ K}$. This value increases to $3.51 \text{ cm}^3 \text{ mol}^{-1} \text{ K}$ at 200 K where it plateaus and the HS state is restored (Fig. 7 top). The SCO in $\mathbf{1C}_4$ is consistent with the crystallographic studies (see above) and shows thermal hysteresis with $\downarrow T_{1/2} = 121 \text{ K}$ and $\uparrow T_{1/2} = 134 \text{ K}$, giving a thermal hysteresis width (ΔT) of 13 K. The observation of thermal hysteresis in $\mathbf{1C}_4$ is surprising as the single crystal structure does not show a temperature-dependent crystallographic phase change from $Pna2_1$, which often accompanies thermal hysteresis in the SCO transition temperature ($T_{1/2}$).⁴² However, it is possible that the hysteresis in this instance is a collective response due to long-range elastic interactions.

Fig. 7 $\chi_M T$ vs. T plots for single crystals of $\mathbf{1C}_4$ and $\mathbf{1C}_{10}$ at a heating rate of 5 K min^{-1} in a 0.1 T external DC field. The red arrow indicates the heating direction and the blue arrow the cooling direction.

1C₁₀ has a $\chi_{\text{M}}T$ value of 3.37 cm³ mol⁻¹ K at 200 K which is expected of a HS Fe(II) system. The value of $\chi_{\text{M}}T$ then decreases slightly to 3.24 cm³ mol⁻¹ K at 123 K before abruptly decreasing to 0.05 cm³ mol⁻¹ K at 111 K. A plateau region is then observed down to 50 K with $\chi_{\text{M}}T$ stabilised at 0.01 cm³ mol⁻¹ K. The sample was then heated from 50 K, and the value of $\chi_{\text{M}}T$ gradually increases to 0.26 cm³ mol⁻¹ K by 116 K before abruptly increasing to 3.42 cm³ mol⁻¹ K at 125 K. The fully HS system is then stable beyond this temperature (Fig. 7 bottom). The SCO in **1C₁₀** is thermally hysteretic as was the case with **1C₄**, although the width of the hysteresis is smaller in the former. For **1C₁₀** $\downarrow T_{1/2} = 117$ K and $\uparrow T_{1/2} = 121$ K, giving $\Delta T = 4$ K, which is 9 K smaller than the 13 K observed in **1C₄**. As with **1C₄**, **1C₁₀** remains in a single crystallographic space group in the HS and LS states.

Infrared spectroscopy

Infrared spectra for **1C₄**, **1C₁₀**, LC₄ and LC₁₀ can be found in Figs. S11-S13. Infrared spectroscopy was conducted at room temperature on single crystals of **1C₄** and **1C₁₀**. Both complexes **1C₄** and **1C₁₀** contain axial thiocyanate ligands which produce characteristic nitrile absorption bands that occur within two distinct regions depending on the spin state of the central Fe(II) ion due to the vibrational differences between electronic states. For Fe(II) the LS ¹A_{1g} and HS ⁵T_{2g} ground electronic states are vibrationally discrete, where the longer coordination bonds of the HS species produce weaker bond force constants, thus oscillating at lower frequencies.⁴³⁻⁴⁵ For Fe(II) species, the nitrile stretch usually appears at ca. 2107 cm⁻¹ for the LS ¹A_{1g} state and between 2040-2070 cm⁻¹ for the HS ⁵T_{2g} state.⁴⁶ Both **1C₄** and **1C₁₀** exhibit strong IR absorption bands at 2043 and 2046 cm⁻¹, respectively, confirming the HS state of both **1C₄** and **1C₁₀** at room temperature consistent with both the crystallographic and magnetic studies.

Conclusions

Complexes **1C₄** and **1C₁₀** vary only by the length of their alkyl chain substituents, which has a significant effect on both their structural and magnetic properties. **1C₄** undergoes a quasi-stepped, semi-abrupt spin-crossover centred at 127.5 K, accompanied by a non-uniform thermal hysteresis where $\Delta T = 13$ K. **1C₁₀** undergoes an abrupt spin-crossover centred at 119.0 K and is also accompanied by thermal hysteresis ($\Delta T = 4$ K). The inclusion of hydrophobic alkyl chain substituents on Fe(II) complexes did not inhibit spin-crossover behaviour, but rather demonstrated high cooperativity which resulted in hysteretic and abrupt thermal spin-crossover in the solid state. This is an encouraging sign for future development of multifunctional materials that might rely on alkyl chains for the incorporation of secondary functionalities such as liquid crystal properties or low-melting point spin-crossover liquids.
